ABSTRACT

Objectives: In order to improve the degree of shared decision making (SDM) experienced by patients, it is necessary to gain insight into the explanations for the differences in these degrees.

Methods: A scoping review of the literature on the explanations for differences in the degree of SDM experienced by patients was conducted. We assessed 21,329 references. Ultimately, 308 studies were included. The explanations were divided into micro, meso, and macro levels.

Results: The explanations are mainly related to the micro level. They include explanations related to the patient and healthcare professionals, the relationship between the patient and the physician, and the involvement of the patient's relatives. On the macro level, explanations are related to restrictions within the healthcare system such as time constraints, and adequate information about treatment options. On the meso level, explanations are related to the continuity of care and the involvement of other healthcare professionals.

Conclusions: SDM is not an isolated process between the physician and patient. Explanations are connected to the

macro, meso, and micro levels.

Practice implications: This scoping review suggests that there could be more focus on explanations related to the macro and meso levels, and on how explanations at different levels are interrelated.

1. Introduction

Over the recent decades, policymakers have been prioritizing shared decision making (SDM) [1–4]. SDM is a process in which the physician and patient consider the information available about the medical problem. This includes treatment options and their consequences, and a consideration of how these fit with the patient’s preferences for health status and outcomes [5–11]. SDM is dependent upon the situation. Patients may be able to choose from several treatment options, or choose not to be treated at all [12–14].

In particular in Western healthcare policy, SDM is seen as an essential process in medical practice and, as such, is incorporated widely [15,16]. In the Netherlands, policymakers are making efforts to improve SDM [17]. Nevertheless, a Dutch study showed no change in the degree of SDM experienced by patients since 2016 [18]. Besides, recent Dutch studies show varying degrees of SDM experienced by patients (e.g. [18–21]). This suggests that not all patients experience SDM, or that they experience this to a lower degree.

Given the efforts made, it may be regrettable that there has been no change in the degree of SDM experienced by patients since 2016. It may also seem a shame that not all patients experience SDM or experience SDM to a lower degree. This seems regrettable because, in theory, SDM aligns with the ethical principle of respecting patients’ autonomy [9,15, 16]. Moreover, research shows that SDM is beneficial for both patients and healthcare providers. These benefits include: increasing the patient’s knowledge about the medical situation; satisfaction with treatment; a reduction of unwarranted variation in healthcare, both in overuse and underuse of care; and better healthcare alignment [9,15, 22]. However, the fact that patients experience different degrees of SDM may be explained by the dependence upon a particular situation. Insight into the explanations for these differences is needed in order to determine whether such a degree is appropriate in a given situation.

We found a systematic review, conducted in 2014, which investigated the barriers and facilitators to SDM reported by patients. This review by Joseph-Williams and colleagues (2014) focused only on explanations from the patient’s perspective [23]. This is a very relevant perspective. However, we are also interested in explanations outside the field of observation for an individual patient, for example that derived from experimental research. In addition, a scoping review, conducted in 2018, which focused on organizational- and system level characteristics that influence the implementation of SDM in general, concluded that organizations that wish to support the adoption of SDM should consider the role of organizational- and system level characteristics [24]. Based on these previous conducted reviews, we expect that a broader perspective might offer additional insight into the differences in the degree of SDM experienced by patients. Besides, we expect based on, among others, the review of Scholl et al. (2018), that ordering the explanations for patients’ experienced degree of SDM into the macro, meso, and micro levels will be helpful [23–25].

In general, the macro, meso, and micro levels are interrelated. The micro level typically concerns the level of individual actors within organizations, the meso level is the intermediate level of organizations, and the macro level is the level of social institutions, the market and the government [26]. In the context of this scoping review, explanations on the micro level focus on day-to-day patient care and the interaction between the patient and the physician, explanations on the meso level focus on the hospital governance and institutional decisions that take place within healthcare organizations, and explanations on the macro level focus on the governmental decisions that determine the organization and funding of the overall healthcare system and its policies [25, 27].

Moreover, the micro, meso, and macro level framing enables us to get insight into the interconnections between explanations across different levels [28].

Against this background, a recent overview of explanations for these differences seems to be lacking. Therefore, we will answer the following research question: “What are the explanations for differences in the degrees of shared decision making experienced by patients?”. In order to answer the research question, we conducted a scoping review with the aim of summarizing and disseminating our research findings in order to explain these differences and to identify gaps in the literature on this subject [29].

2. Methods

The research protocol was registered on OSF.io (<https://doi.org/10.17605/OSF.IO/GQ7EA>) and the scoping review was guided by the methodological framework developed by Arksey and O'Malley (2005).

This framework consists of five stages: 1) identifying research questions; 2) identifying relevant studies; 3) selecting studies; 4) charting the data; and 5) collecting, summarizing, and reporting the results [29]. After identifying the research question as mentioned in the introduction, the search strategy was refined and finalized in collaboration with an experienced librarian. For the identification of relevant studies, we used broad conceptualizations of the degree of SDM experienced by patients. Therefore, the search strategy focused on Boolean connections (AND, OR) of different combinations for ‘shared decision making’, ‘patients’ experiences’, and ‘humans and adults’. Searches were conducted up to December 10th, 2021, in three bibliographic databases, PubMed, Embase, and CINAHL (see Tables 1–3 for the final search strategies). An update of the literature search was conducted up to May 19th 2023. The search results were imported into Rayyan and yielded $n = 11,428$ for Pubmed, $n = 17,134$ for Embase and $n = 7857$ for CINAHL (see Fig. 1). The studies that we identified, screened, and included were reported based on the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines [30].

2.1 Eligibility and exclusion criteria

Two authors (AZ and MB) independently screened all the titles and abstracts of the remaining studies taken from the initial search ($n = 17,913$). For the update, the first author (AZ) screened all the titles and abstracts of the remaining studies ($n = 3416$), and three authors (NB, RF and JD) screened a sample totaling 20% ($n = 689$). Only 4% of the sample initially yielded a conflicting decision. Disagreements regarding whether to include a study were resolved by discussion between two authors (AZ and NB). This occurred for instance, when it was not completely clear which measure was used for SDM.

[Table 1], [Table 2], [Table 3], [Figure 1]

The review was limited to the following eligibility criteria. Firstly, the patient’s degree of SDM experienced, and explanations for this, which were measured empirically, both in a qualitative and quantitative manner. Besides, quantitatively measured explanations had to be statistically tested. And, secondly, people aged eighteen years and older were the subjects of the studies. An operationalized definition of SDM was necessary for the screening. SDM has been defined in several ways in the literature [10,31]. As a consequence some studies have been using the term in an unfamiliar manner [32]. In line with the description of SDM, outlined in the introduction, and derived from a previous scoping review about SDM in surgery, and a systematic review about the term SDM, the following working definition was determined as the most appropriate: “an approach where clinicians and patients share the best available evidence (both clinical information and patients’ preferences for health status and outcomes) when faced with the task of making treatment

decisions, and where patients are supported in considering treatment options and achieving informed preferences” [9,10,32]. In order to reduce the risk of including studies inappropriately, studies were excluded when they did not explicitly mention how they define SDM. Studies were also excluded when the degree of SDM experienced was quantified among multiple stakeholders, for example patients and reporting their experiences. Quantitative studies were excluded when no total score was measured for SDM experienced by patients. Qualitative studies, furthermore, were excluded when more broad questions were asked about making treatment decisions or when the article was loosely framed as being about SDM. Lastly, we excluded studies of which the full texts were not available, and we excluded reviews because we may assume that our search includes any relevant included study in reviews.

2.2 Data extraction

After reading the full texts, the first author (AZ) charted the data according to the following outcome measures: details of publication information; study method; sample type; study setting; and, relevant findings, by which we mean explanations for the degree of SDM experienced by patients that were tested empirically. When screening the full texts, it became clear that most of the articles examined empirical relationships between the various independent variables and the degree of SDM experienced by patients. These did not examine the more general explanations for, or hypotheses about, these degrees of SDM. All these variables, tested empirically, and relating to the degree of SDM experienced that were found in the literature, have been included. The first author (AZ) grouped all variables in Microsoft Excel (2019) according to the following categories: patient characteristics, for example, age, gender, education level, and health literacy; health conditions, for example, disease, health status, and emotional distress; healthcare professional characteristics such as age and gender; tools, for example, decision aids and prompt lists; training for healthcare professionals; training for patients; the involvement of relatives and friends; the involvement of another healthcare professional, for example nurses, GPs, and doulas; contextual factors such as time, culture, guidelines, and costs; the SDM process, such as, choice awareness and preparation on SDM; information; the relationship between the patient and the physician, such as trust, and shared history; healthcare professionals’ skills, for example in communication; the patient’s preference for involvement, and other factors such as their self-management (e.g. [33]) or condition management skills (e.g. [34]); patients’ beliefs or convictions (e.g. [35,36]); patients’ self-efficacy (e.g. [37–40]); patient activation (e.g. [41]); missing cognitive testing data [42]; the region where a consultation took place [43,44] or the extent of team-interaction (e.g. [45]).

Subsequently, we organized the broader categories of explanations into macro, meso, and micro levels. An explanation for the degree of SDM experienced by patients, related to the macro level, is, for example, time constraints, which is mentioned within the category ‘contextual factors’. An explanation for the degree of SDM experienced by patients related to the meso level is, for example, the involvement of a nurse in the SDM, which is mentioned within the category ‘involvement of another healthcare professional’. Finally, explanations related to the micro level are for example, the patient’s educational level, which is mentioned within the category ‘patient characteristics,’ or trust, mentioned within the category ‘patient-physician relationship’.

3. Results

3.1. The characteristics of the studies we included

Ultimately, 308 articles were included (see Fig. 1). Table 4 provides an overview of the studies included and their characteristics. Most of these studies were conducted in the United States (n = 113) and in European countries, such as the Netherlands (n = 47), Germany (n = 33) and the United Kingdom (n = 21). The quality of the studies varied. Studies were conducted with different designs,

research methods, and ways of sampling. The majority of the studies used a questionnaire to measure the degree of SDM experienced by patients (n = 209) (see Table 4).

3.2. The main findings

The literature searches revealed various empirically tested explanations for differences in the degree of SDM experienced by patients (see Table 4). On the macro, meso, and micro levels, we found both limiting and promoting factors for the degrees experienced. Fig. 2 provides a schematic representation of the key findings. Ordering explanations into the macro, meso, and micro levels allowed us to provide a framework in order to gain insight into the explanations for differences in the degrees of SDM experienced. This enabled us to gain insight into the explanations that could be managed, and to identify gaps in the literature.

3.3. Explanations on the macro level

Studies report a few explanations for differences in the degree of SDM experienced on the macro level. These studies outline explanations related to restrictions within the healthcare system and its policy. Evidence based protocols to guide clinical decisions (e.g. [46–48]), insurance coverage, or, rather, the lack of it (e.g. [36,49–54]), and financial constraints (e.g. [46,55–58]) may limit treatment options (e.g. [46]). In addition, constraints on the time available to make an informed decision (e.g. [46–48,57–80]) and access to healthcare (e.g. [33,63,81]) are mentioned.

In addition, many studies mention explanations related to receiving adequate information about treatment options (e.g. [19–21,35,40,56, 57,59,61,64,65,67,69–71,74,76,78,82–123]). For example, information is conflicting (e.g. [35,46,64,67,69,87,88,114,124]). In short, inadequate information makes it difficult for patients to consider treatment options.

3.4. Explanations on the meso level

Studies also outline explanations for differences in the degree of SDM experienced by patients on the meso level, which is of healthcare institutions. These explanations are related to continuity of care (e.g. [48, 54,59,78,125]). Examples of factors which could allow less space for shared decisions include: standardized pathways (e.g. [47,126]), the structured nature of the consultation (e.g. [69,122]), scheduling restrictions (e.g. [46,58,67]), a lack of continuity in treating physicians (e.g. [20,55,58,59,63,127]), restricted team-interaction (e.g. [45]), and providing information too late during the process of making a treatment decision (e.g. [20]).

In addition, the involvement of another healthcare professional is mentioned (e.g. [19,54,55,58,60,88,89,110,113,128–136]). For example, case managers could prepare patients for the process of SDM (e.g. [128]), nurses could repeat and/or explain information about treatment options (e.g. [19,129–131,133]), and they could converse with patients about their preferences, values, and needs (e.g. [131,137]), and general practitioners (GPs) could offer supportive care to patients who have to make a treatment decision in secondary care after a cancer diagnosis [138,139].

3.5. Explanations on the micro level

Many studies outline explanations for differences in the degree of SDM experienced on the micro level of patient care and interactional influences. Part of the explanations relate to clinical differences between patients (e.g. [33,37,38,47,49,50,60,61,90,113,116,140–172]), and are determined by the stage, chronicity, or complexity of the illness (e.g. [37,38,57,60,122,156,163,165,172]). Some of these explanations are of interest in determining whether differences in the degree of SDM are warranted. Nevertheless, the nature of the initial diagnosis could lead to patients perceiving a lack of treatment options (e.g. [38,47,122,140]). Indeed, diagnosis or a treatment decision may entail emotional distress (e.g. [35,62,77,130]). It is important

that patients accept their diagnosis before SDM can take place (e.g. [62,129]). Furthermore, factors related to the patient and the healthcare professional, the relationship between the patient and the physician, and the involvement of relatives, could explain differences in the degrees of SDM.

[Table 4], [Figure 2]

3.5.1. Patient-related factors

Many studies mentioned patient characteristics which are related to differences in patients' experienced degree of SDM, such as: age (e.g. [35,52,57,62,63,73,113,116,149,150,152,161,162,165,170, 172–186]); gender (e.g. [52,116,142–144,154,156,170,172,175,176, 182,187]); ethnicity (e.g. [49–51,53,176,188–193]); and employment status (e.g. [52,162]). For instance, several studies show that women experience a higher degree of SDM than men (e.g. [142,144,156,175, 176,187]). In addition, these mentioned too, patients' educational level, level of health literacy (e.g. [35,36,39,49,50,57,62,75,127,143,149, 161,162,165,172,187,194–201]), and, in one study, patients' level of e-health literacy [202]. Patients who have a good understanding of their illness (e.g. [69,77,188]) and understand information about treatment options, typically experience higher degrees of SDM (e.g. [57,62,82, 203]). Accordingly, many studies have been conducted to evaluate the effectiveness of information tools (e.g. [128,204–225]), such as decision aids (e.g. [204–213,216,224–228]), in order to improve the degree of SDM experienced.

Furthermore, patient communication is mentioned (e.g. [62,69,79, 98,104,229,230]). Patients have to be able to express themselves (e.g. [62,98,117,230,231]) and to ask questions (e.g. [69,98,117]). One complicating factor for patients is speaking a language other than that of the physician (e.g. [140,232]). Personal beliefs and convictions are also specified (e.g. [35,36,63,71,74,84,98,140,233–235]). For example, patients' attitudes towards their healthcare professionals' age, gender, and ethnicity (e.g. [36,233,236]) or their preference for a paternalistic approach by the healthcare professional (e.g. [35,74,98,146,234,237]) could have an impact upon their intentions of engaging in SDM. Patients who prior to choosing a treatment, prefer SDM instead of a paternalistic approach by the healthcare professional, could experience a higher degree of SDM than those patients who did not prefer SDM (e.g. [64,67, 146,179,238–240]). In line with that, patients should be aware of, and understand the process of SDM (e.g. [46,56,62,65,80,128,241,242]), should be prepared (e.g. [38,59,61,197]), and should be aware of treatment options (e.g. [56,65,66,82,87,129]). Another explanation for differences in the degree of SDM experienced by patients is the patients' perceived health status (e.g. [51,52,75,153,156,162,176,178,243]). Several studies show that patients with higher perceived health status experience a higher degree of SDM (e.g. [51,153,162,176,243]).

3.5.2. Healthcare professional related factors

Several studies mentioned factors related to the healthcare professional which affect the degree of SDM experienced by patients (e.g. [34, 244–247]). Healthcare professionals could have an overbearing influence upon SDM (e.g. [35,55,71,72,78,84,87,92,99,117,248,249]), for example by recommending a treatment (e.g. [248,250,251]), or by not offering treatment options (e.g. [104,110,111,155]). However, the professionals are obliged to create an environment of safety and trust [61,91,201]. Therefore, the manner in which healthcare professionals communicate is important (e.g. [19,38,39,45,55,57,59,63,68,72,75,76, 79,83,91,92,95,97–99,107,110,113,118,120,124,126,236,252–257]). This could include the use of clear language, including the absence of medical jargon (e.g. [57,61,75,95,98]), showing empathy (e.g. [45,54, 76,199,236]), and listening to (e.g. [59,78,79,99,107,120,124,126,127, 254,258]), and answering,

questions (e.g. [68,80]). Accordingly, studies have been conducted to evaluate training courses which aim to increase the implementation of SDM (e.g. [222,228,259–269]).

3.5.3. The relationship between the patient and physician

Many studies address the relationship between the patient and physician. In general, patients who experience a good relationship experience a higher degree of SDM (e.g. [33,48,58,59,61,67,77,81,82, 85,86,128,236,270–274]). As an aspect of the patient-physician relationship, patients' trust in their physician is an important factor (e.g. [114,118,120,121,127,242,275–277]). Patients who trust their physician could experience a higher degree of SDM (e.g. [59,61,98,100,126, 140,188,233,271,278,279]), because they feel confident to ask questions and to consider different treatment options (e.g. [61,100,233, 279]). However, patients who trust their physician tend to have confidence in their physician and so leave the treatment decision to their physician (e.g. [47,56,112,127,140]). Another aspect of the patient-physician relationship are stigmas (e.g. [54,189,280]). For example, stigma about HIV pre-exposure prophylaxis, as it relates to black transgender women, results in stereotyping, which undermines trust and deters SDM in this area [280].

3.5.4. The involvement of relatives

Another explanation on the micro level is the involvement of relatives in SDM (e.g. [54,113,118,127,281]). Patients could experience the involvement of relatives as supportive (e.g. [21,33,35,58,60–62,83,84, 86,89,98,114,129,130,140,278]) if they feel emotionally supported by them and consider treatment options with them (e.g. [21,35,62,84,98, 129,140]). In addition, relatives could function as interpreters (e.g. [61, 98]). This may lead to greater patient honesty, trust, and comfort, and thereby serve to improve their experience of SDM (e.g. [140]). However, there are patients who experience the involvement of relatives as opposing or complicating (e.g. [21,55,84,87]). For example, when they feel excluded (e.g. [55]) or when they experience pressure from their relatives to choose a specific treatment (e.g. [84,87]). The involvement of peers can also contribute to the degree of SDM experienced (e.g. [280]).

3. Discussion and conclusion

4.1. Discussion

This scoping review aimed gaining insight into explanations for the differences in the degree of SDM experienced by patients. It also aimed to identify gaps in the literature. We found a wide variety of explanations that are related to these differences and structured them to a macro, meso, and micro level. However, we also found explanations, which were tested empirically, and which were not significantly related to the differences in the degrees of SDM (e.g. [180,194,282–338]). Nevertheless, most studies address explanations for these differences which are related to the micro level. In the literature, the nature of the initial diagnosis, patient-related factors, factors related to the healthcare professional, the relationship between the physician and patient, and the involvement of relatives are mentioned. However, the studies address fewer explanations for the differences in the degree of SDM on the meso and macro levels. On the meso level, studies outline explanations related to the continuity of care and the involvement of other healthcare professionals. On the macro level, studies outline explanations related to restrictions within the healthcare system and receiving adequate information about treatment options. Despite all efforts over the last decade to improve SDM, these findings are consistent with the findings of Joseph-Williams and colleagues from 2014. It was already clear, solely from the patients perspective, that relatively little was known about the relationship between factors on the different levels of the healthcare system and healthcare organizations, and the degree of SDM [23].

Explanations for the differences in the degrees of SDM have been presented in specific categories and isolated levels in order to gain insight into explanations that could be managed on the different levels. Undoubtedly, that is an oversimplification of the reality because the macro, meso, and micro levels are interrelated [27]. Based on our results, explanations are linked to a macro, meso, and micro level, while the explanations could be interrelated with each other. For a better understanding of differences in the degree of SDM experienced by patients, the mechanisms behind these explanations are important. For example, the way patients' beliefs or prejudices affect their trust in healthcare professionals could be an explanation for the degree of SDM experienced. Ahmad and colleagues (2021) suggest that patients' perceptions concerning the gender and ethnicity of their healthcare professional offering diabetes care shapes their trust in them and indirectly influences their participation in SDM [233]. Another example concerns the mechanisms behind the lack of time to make an informed decision. The lack of time can be a barrier to the degree of SDM experienced by patients in several ways. For instance, the lack of time can result in physicians being stressed, which in turn may lead to a reduced level of information sharing, and a reduced rate of patient enquiries [60].

We conclude that SDM is not an isolated process between the physician and patient, as frequently assumed in healthcare policy. In line with Moleman et al. (2020) [82], we are convinced that understanding SDM as a process of interactions that transcend the conversation between the physician and patient in the consulting room offers new opportunities to understand better the differences in the degree of SDM experienced by patients and offers new opportunities to increase the degree of SDM experienced by patients.

4.2. Practice implications

This scoping review suggests that SDM is viewed too narrowly. Studies to date, focus mainly on explanations related to the micro level. Accordingly, this scoping review provides implications for researchers and policymakers. In line with the conclusion of Scholl et al. (2018) that organizations should consider the role of organizational- and system level characteristics in order to improve the implementation of SDM [24], researchers and policymakers could focus more on explanations related to the macro and meso levels as well, in order to gain more insight into explanations for the degrees of SDM and to increase these degrees experienced by patients. Degrees which have remained stable despite efforts on the micro level. In addition, it is important that the interrelation between the macro, meso, and micro levels are kept in mind and thereby the interrelation of explanations for the differences in the degree of SDM experienced by patients.

Therefore, in general, further research could focus on the way explanations are interrelated and how they affect the degree of SDM experienced by patients. For instance, several studies, mainly based on interviews with patients, indicate that they require more time during consultations to make an informed decision (e.g. [46,47,57–75]). However, these findings do not seem to be confirmed through experiments. Therefore, more experimental research could help to understand whether extending consultation time actually contributes to the degree of SDM experienced by patients. In doing so, it would help to understand differences in degrees of SDM by also understanding how extending consultation time is related to mechanisms on the meso and micro levels since these levels are interrelated. Subsequently, it could be relevant to research to what extent the associated costs for extending consultation time outweighs benefits for patients and healthcare providers. Factors such as the satisfaction with any decision, the reduction of unwarranted variation in healthcare, and better healthcare alignment, could be considered [9,15,22]. Related to cost-benefit trade-offs, such experimental research could possibly include the use of real-time video conferencing technology, or telemedicine, since telemedicine is increasingly seen as a strategy for healthcare organizations to save costs [339].

Based on the results of this scoping review, improvements in SDM could be achieved if policymakers could be made more aware of mechanisms which have connections to the micro, meso, and macro levels when implementing interventions such as decision aids or a training for healthcare professionals. This conclusion is in line with that of Scholl et al. (2021). They suggest, after evaluating a multi-component SDM implementation program, that successful implementation of SDM on the department level requires changes on the organizational level too [340]. Policies could be adjusted specifically on the macro and meso levels in order to have an impact upon the degree of SDM experienced by patients on the micro level. Therefore, we expect minor changes in the degrees of SDM experienced when interventions are not embedded on the macro, meso, and micro levels.

For instance, the literature suggests that on the micro level, patients understanding of treatment options is important (e.g. [57,62,82]). Many studies have been conducted to evaluate the effectiveness of information tools (e.g. [128,204–221]), such as decision aids (e.g. [204–213,216]) in order to improve patients understanding of treatment options and thereby the degree of SDM experienced by patients. However, patients may still experience limiting factors. On the micro level, for example, this could be due to a physician adopting a didactic attitude. On the meso level, this could be due to the structured nature of consultations. And, finally, on the macro level, this could be due to time constraints.

This scoping review has several limitations. Even though two authors screened all articles by title and abstract, it might be possible that we missed relevant articles. However, the conservative eligibility and exclusion criteria contribute to the quality of the scoping review by reducing the risk of including studies inappropriately. Additionally, due to the substantial number of articles included, we had to make choices and could not do justice to every explanation. Therefore, it might be possible that we missed some explanations. Nevertheless, we are convinced that we outlined the most important explanations and provide a comprehensive review of explanations for differences in the degrees of SDM experienced by patients.

Another limitation is related to organizing the broader categories of explanations into macro, meso, and micro levels. Some explanations are related to several levels. For example, 'information'. On the micro level patients should understand information about treatment options. On the meso level patients must receive information about treatment options in a timely manner, which could be seen as a responsibility of the healthcare organization that establishes pathways and, on the macro level it is important that reliable information about treatment options exists at all, which could be seen as a responsibility of the government. Nevertheless, the macro, meso, and micro levels provide a helpful framework for ordering the explanations for patients' experienced degree of SDM and for identifying gaps in the literature on this subject.

Furthermore, the findings came from a wide range of studies each with its own study design. As a result, the quality of the studies included is variable. Furthermore, as mentioned in the introduction, SDM is dependent upon different situations. Therefore, the explanations cannot be applied to every context. However, this scoping review gives an overview of explanations for differences in the degrees of SDM experienced by patients and outlines the relevant gaps in the literature.

4.3. Conclusion

Based on literature, we conclude that SDM is not an isolated process between the physician and patient. Explanations for differences in the degrees of SDM experienced by patients interact on macro, meso, and micro levels. SDM is a process of interactions that transcends the conversation between the physician and patient in the consulting room. Seeing it as such offers new opportunities to understand better the different degrees of SDM experienced and offers new opportunities for improvements in these degrees. In order to improve the degree of SDM experienced by patients, this scoping review suggests that researchers and policymakers could focus more on explanations related to the macro and meso levels, and on how explanations on different levels are interrelated.

Funding

This research did not receive any specific grants from funding agencies in the public, commercial, or not-for-profit sectors.

Figure 1 Flow diagram of the study selection.

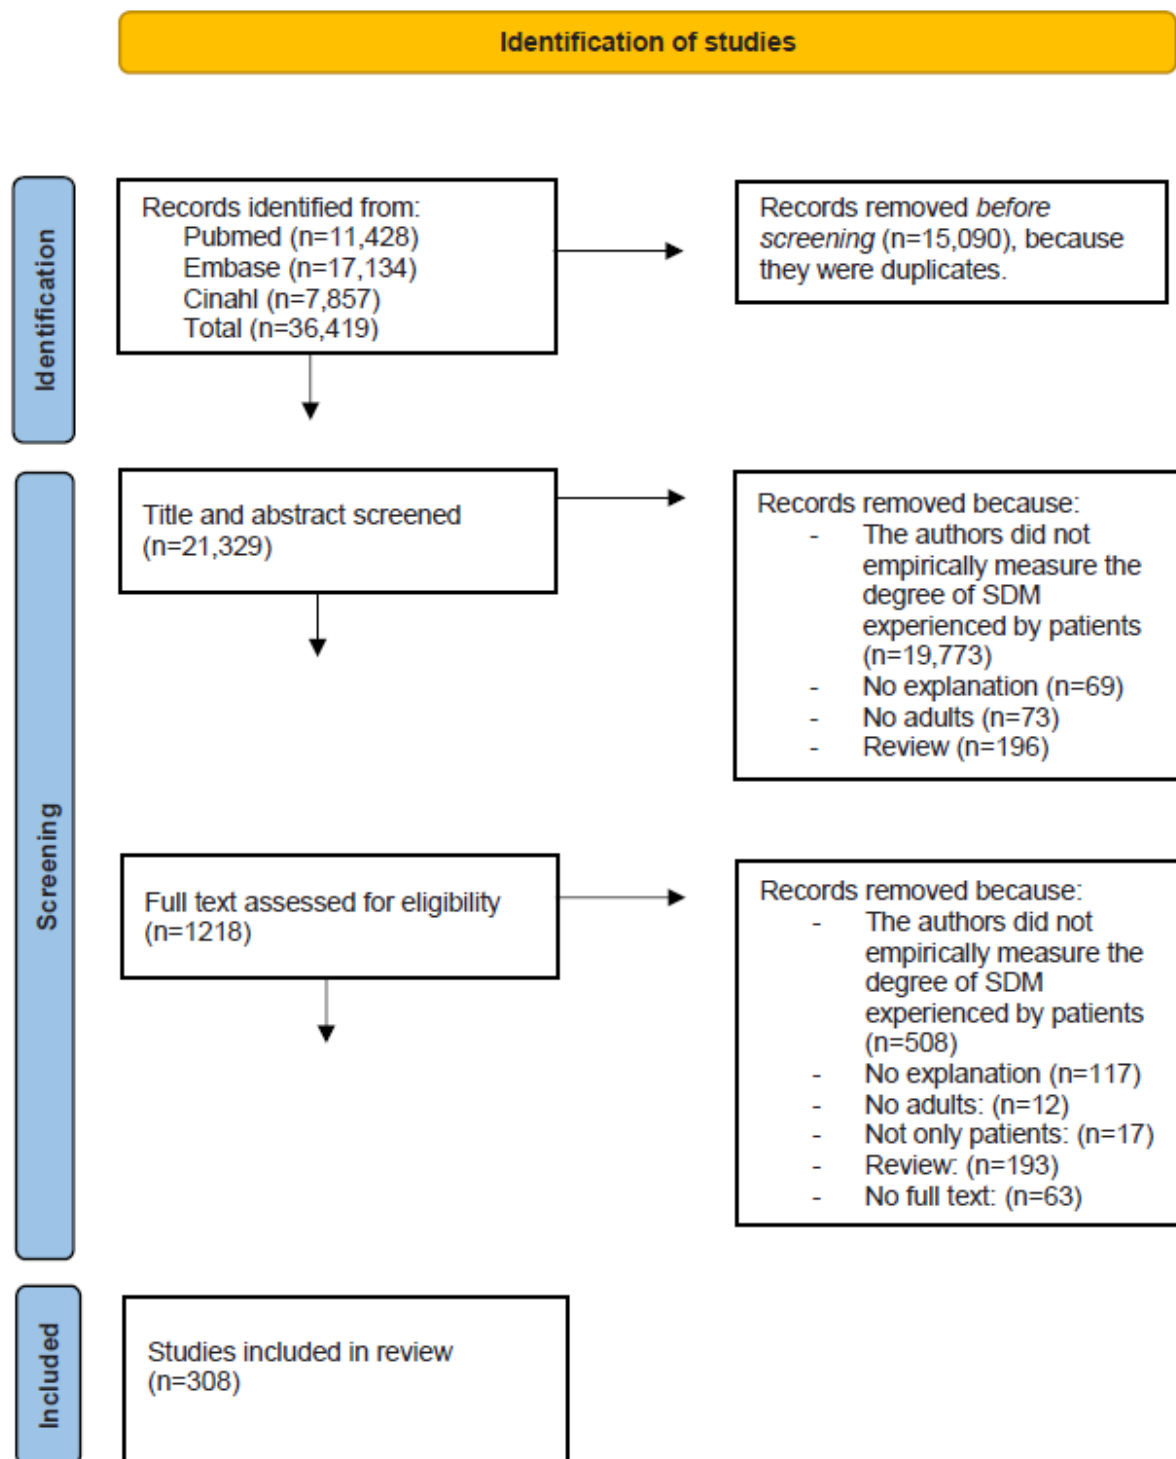

Table 4 Overview of the studies included.

First author, year of publication, country of origin, and citation number	Design and method (s) used to measure the degree of SDM experienced by patients	Type of sampling* and patient sample size (n) among whom the degree of SDM has been measured	Disease or healthcare setting	Categories of the empirically tested explanation (s) for the degree of SDM experienced by patients
1 Aarts, J.W.M., 2021, United States,[206]	Experimental, questionnaire	Nonprobability sampling, n = 57	Heavy menstrual bleeding and/or symptomatic uterine fibroids	• Tools
2 Abate, A.W., 2023, Malawi, [54]	Observational, questionnaire and interviews	Nonprobability sampling, n = 423 and n = 21	Mental illness	• Patient characteristics • Contextual factors • Involvement of another healthcare professional • Healthcare professionals' skills
3 Abousheisha, A.A., 2021, Malaysia,[207]	Experimental, questionnaire	Nonprobability sampling, n = 378	Major depressive disorder	• Tools
4 Adarkwah, C.C., 2016, Germany,[311]	Experimental, questionnaire	Nonprobability sampling, n = 304	Cardiovascular risk	• Tools
5 Ahmad, T., 2021, Canada, [233]	Observational, interviews	Nonprobability sampling, n = 28	Diabetes	• Patient-physician relationship • Patient characteristics
6 Albaroudi, A., 2022, United States,[193]	Observational, questionnaire	Nonprobability sampling, n = 568368	Alzheimer disease	• Training for healthcare professionals
7 Alegria, M., 2018, United States,[305]	Experimental, questionnaire	Nonprobability sampling, n = 312	Psychotherapy and pharmacologic services	• Tools
8 Allen, J. D., United States, 2020,[208]	Experimental, questionnaire	Nonprobability sampling, n = 45	Prostate cancer screening	• Tools
9 Almario, C.V., 2016, United States,[322]	Experimental, questionnaire	Nonprobability sampling, n = 371	Active gastrointestinal symptoms	• Tools
10 Almario, C.V., 2022, United States,[326]	Experimental, questionnaire	n = 128	Inflammatory bowel disease	• Tools
11 AlSarhan, M.A., 2021, Saudi-Arabia,[244]	Observational, questionnaire	Probability sampling, n = 144	Dental implants	• Patient characteristics • Healthcare professionals characteristics
12 Aminaie, N., 2019, Iran,[282]	Observational, questionnaire	Nonprobability sampling, n = 328	Breast cancer	• Patient preference for involvement • Patient-physician relationship • Contextual factors • Health conditions
13 Andersen-Hollekim, T., 2021, Norway,[47]	Observational, interviews	Nonprobability sampling, n = 19	Breast cancer, prostate cancer, and malignant melanoma	• Information
14 Ankersmid, J.W., 2023, the Netherlands,[115]	Observational, interviews	Nonprobability sampling, n = 22	Breast cancer	• Patient preference for involvement • Tools • Involvement of another healthcare professional • SDM process • Information • Health conditions • Involvement of relatives
15 Ankoekar, A., 2021, the Netherlands,[238]	Observational, questionnaire	Nonprobability sampling, n = 25	Extensive-stage small-cell lung cancer	• Patient characteristics • Health conditions • Healthcare professionals' skills
16 Aoki, Y., 2019, Japan,[137]	Experimental, questionnaire	Nonprobability sampling, n = 88	DSM-IV diagnosis of major depressive episode	• Health conditions • Patient characteristics • Contextual factors • Tools
17 Aoki, Y., 2019, Japan,[90]	Observational, interviews	Nonprobability sampling, n = 10	Psychiatric (e.g. bipolar disorder, and depression)	• Patient characteristics • Health conditions • Involvement of relatives
18 Attanasio, L.B., 2018, United States,[49]	Observational, interviews	n = 2787	First childbirth	• Patient characteristics • Health conditions • Healthcare professionals' skills
19 Baca-Dietz, D., 2020, United States,[252]	Observational, interviews	Nonprobability sampling, n = 6	Chronic condition	• Health conditions • Patient characteristics • Contextual factors
20 Baicus, C., 2019, Romania, [143]	Observational, questionnaire	Nonprobability sampling, n = 665	Atrial fibrillation or/and collagen-vascular diseases	• Tools
21 Baijens, S.W.E., 2018, the Netherlands,[283]	Experimental, questionnaire	Nonprobability sampling, n = 62	Childbirth	• Tools
22 Bansback, N., 2021, Canada, [209]	Experimental, questionnaire	Nonprobability sampling, n = 45	Clinically isolated syndrome, primary-progressive MS, or secondary-progressive MS	• Tools
23 Barr, P.J., 2019, United States, [312]	Experimental, questionnaire	Nonprobability sampling, n = 24	Depression	• Tools
24 Barr, P.J., 2016, United States, [144]	Observational, questionnaire	Nonprobability sampling, n = 972	Depression	• Patient characteristics • Health conditions
25 Bartlett, S.J., 2020, United States,[214]	Observational, questionnaire and interviews	Nonprobability sampling, questionnaire n = 196 and interviews n = 9	Rheumatism	• Tools
26 Becher, S., 2021, Germany, [38]	Experimental, interviews	Nonprobability sampling, n = 18	Schizophrenia or schizoaffective disorder	• Health conditions • Healthcare professionals' skills • SDM process • Other
27 Beyene, L.S., 2019, Norway, [91]	Observational, interviews	Nonprobability sampling, n = 16	Mental care (e.g. depression, psychosis, emotional unstable personality disorder, and suicidal)	• Healthcare professionals' skills • Information
